Parker PSA Nitrogen Gas Generation Systems

What is a buffer vessel?

Fact Sheet

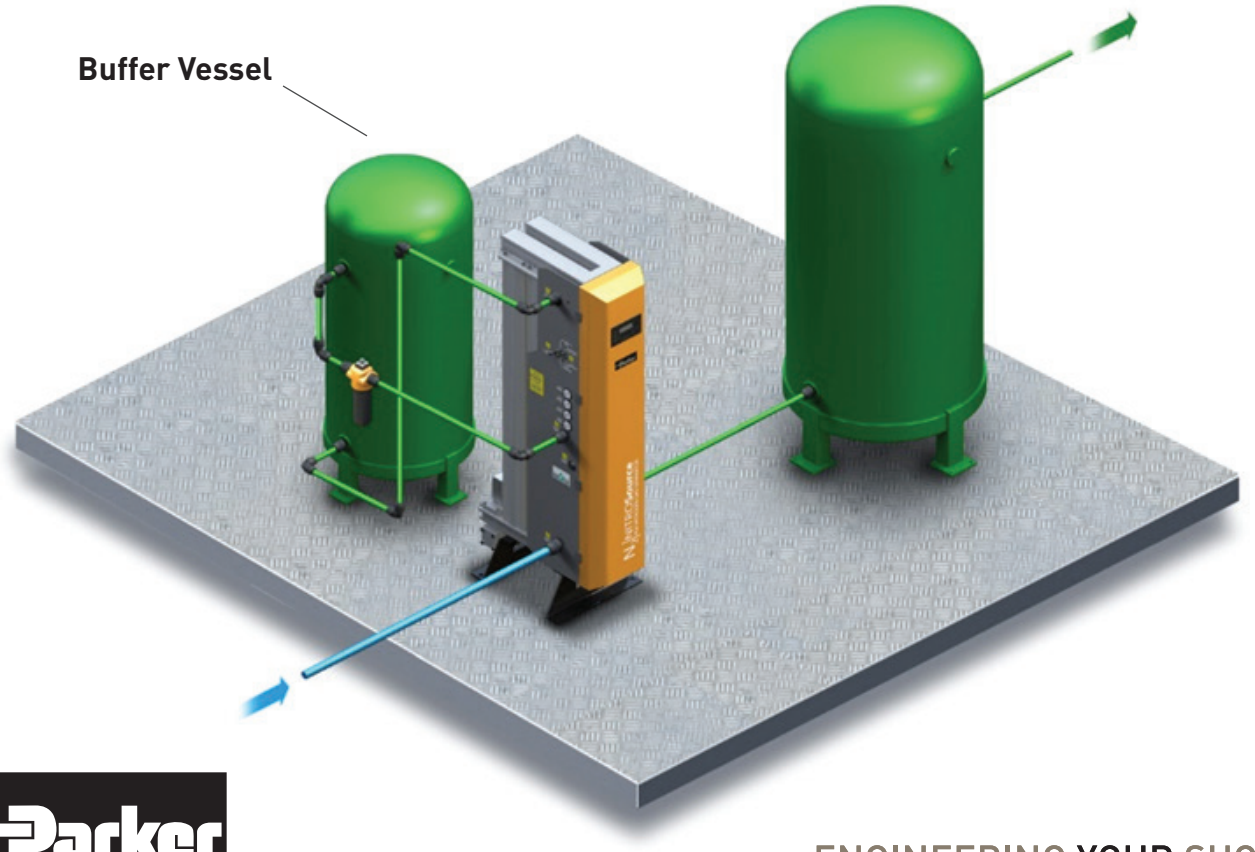
Parker NITROSource and NITROSource Compact, pressure swing adsorption technology, (PSA), nitrogen gas generators, are specified with a buffer vessel for their correct operation.

What is a buffer vessel, how does it work and why is its size important?

A buffer vessel is required for several reasons:

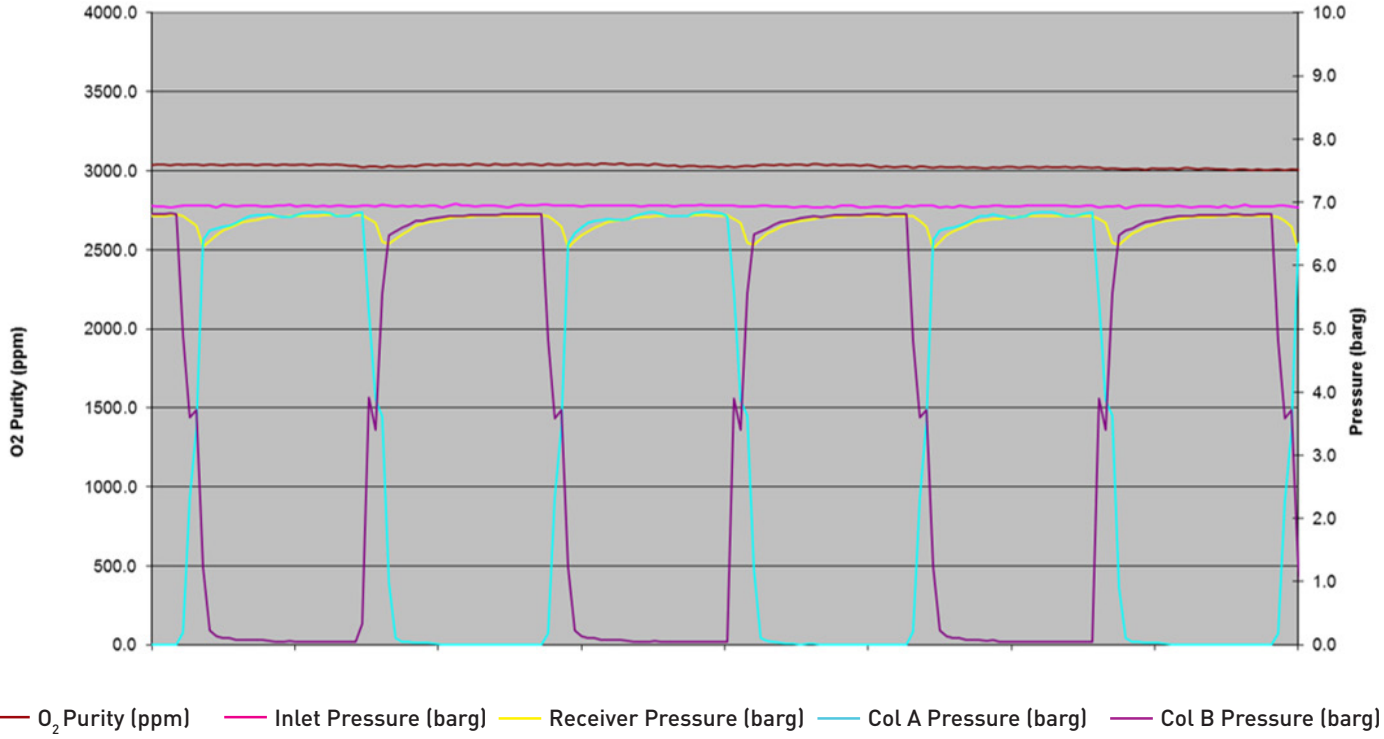
1. During the generation phase of the NITROSource and NITROSource Compact, the purity, pressure and flow varies slightly from beginning to the end of the cycle. In this instance the buffer vessel ensures that the purity, pressure and flow measured by the on-board instrumentation is consistent and stable. Furthermore, the application will also benefit from this very stable output.
2. The NITROSource PSA employs a productivity improving and energy saving technology called “Equalisation”.
   At the end of every half cycle, just before the columns of CMS, (carbon molecular sieve), that are “on-line” are about to change over to “regeneration”, all inlet, outlet and exhaust valves close. When this happens “Equalisation” valves that connect both on-line and regeneration columns of CMS open allowing equalisation of pressure, for all columns of CMS, by transfer of nitrogen and inlet compressed air. This saves nitrogen and air whilst also starting the columns of CMS that are about to come online partially pressurised, so they begin operating at maximum nitrogen productivity sooner in the cycle.

   This equalisation phase lasts for 4 seconds. During equalisation, no nitrogen gas is output from the generator. In this case, supply to the application is fed from the buffer vessel to ensure continuous nitrogen gas flow.
3. Immediately the equalisation phase is completed, the inlet, outlet and exhaust valves open on the appropriate sets of columns of CMS and the equalisation valves close. At the same time back-flow of nitrogen gas from the buffer vessel assists the columns of CMS coming on-line to rapidly achieve maximum operating pressure and hence maximum productivity conditions as quickly as possible.



ENGINEERING YOUR SUCCESS.

Plot of pressure and purity for NS-PSA with buffer vessel



The stable outlet purity can be observed as the brown line whereas the yellow line represents maximum and minimum pressures within the buffer vessel.
To achieve a very stable outlet pressure, the generator's integral pressure regulator is generally set a 0.5 barg below the minimum buffer vessel pressure.

It is important in maintaining stability of outlet nitrogen pressure, flow and purity that the correct size buffer vessel is selected for installation with the chosen nitrogen generator.

Buffer vessel sizes

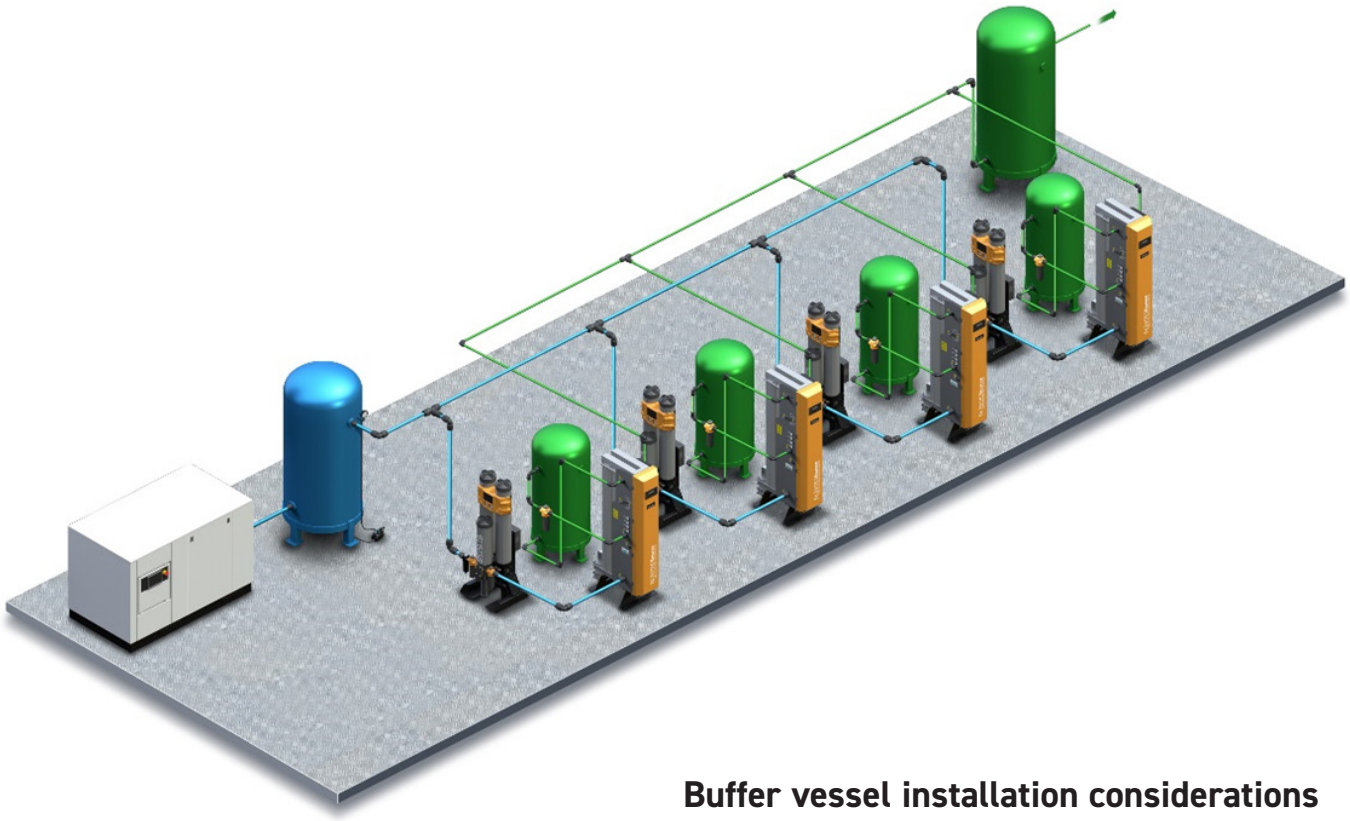
NITROSource Model	Buffer vessel size (litres)
N2-20P	250
N2-25P	500
N2-35P	500
N2-45P	750
N2-55P	750
N2-60P	750
N2-65P	1000
N2-75P	1000
N2-80P	1000

Choosing a slightly bigger volume buffer vessel than recommended doesn't create any problems but selecting a vessel too far below those indicated could cause issues with generator operation with regards to outlet nitrogen pressure and delivered gas maximum remaining oxygen content.

Do I have to use one buffer vessel per generator?

In theory the answer to this is no. If the buffer vessel is sized correctly for the number of generators connected to it, then it should work.

The really huge drawback for using just one buffer vessel is that if one of the generators connected to it has a problem with out of specification gas purity, all of the nitrogen generators connected to it will sense the high oxygen content gas through their individual, integral oxygen analyser. This means there is a very high probability that all of the generators will then trip out on high oxygen content alarm and all gas output will be lost.



Buffer vessel installation considerations

What type of buffer vessel should I use?

Normally, new, clean, dry carbon steel air receivers are ideal for use as nitrogen generator buffer vessels. The norm is for vertical orientation vessels, but horizontal vessels are fine too.

Sometimes galvanised, stainless steel or internally coated vessels are specified. It is important to ensure that any internal vessel treatment does not create contaminants that could affect the nitrogen gas purity.

Important - The buffer vessel must be rated for the maximum compressor pressure in the system.

Buffer vessel connections and components

Buffer vessels should be equipped with standard pressure vessel components - inlet and outlet ports, pressure gauge, safety pressure relief valve, drain port and inspection ports.

Although the nitrogen fed to the buffer vessel is extremely dry, typically better than -600 °C pressure dew point, it is good practice to feed the inlet nitrogen to the lowest port and the outlet nitrogen from the highest.

The drain valve is useful for purging the vessel during commissioning and inspection but if a standard ball valve is fitted, it may be advisable to fit a blanking plug to the valve outlet to prevent the release of nitrogen gas into the surrounding area through accidental or deliberate tampering of the valve.

If sited within a confined space, without adequate ventilation, when purging the buffer vessel is required it is essential to fit a suitable flexible hose to the drain valve to enable venting to a safe area.

Depending on where the buffer vessel is sited it may also be a requirement to pipe the safety pressure relief valve outlet port to a safe area. In this case a safety valve with threaded outlet port is advisable.

It is essential that there are adequate warning signs fitted to the buffer vessel, informing personnel that it contains a potentially asphyxiant gas.

How close should the buffer be to the generator?

In theory, providing the inlet and outlet pipe-work to the buffer is adequately sized to prevent pressure drops, it doesn't really matter.

Practically, for ease of commissioning, monitoring and to reduce installation costs, the buffer is generally sited adjacent to the generator.

In instances where space is at a premium, within a plant room for example, the buffer vessel(s) can be located outside, provided painting with a suitable coating to prevent external corrosion from exposure to the weather is employed. Because the nitrogen is so dry, in all but the most extreme of low temperature locations, there should be no precipitation of moisture from the nitrogen gas internally.

Isolation of the buffer vessel

Suitable valves fitted to the inlet and outlet ports of the buffer vessel should be used to enable isolation for de-pressurisation purposes, for routine vessel inspection, for example.

Included with the nitrogen generator is a buffer vessel return line filter. This is installed to prevent particulate from entering the generator nitrogen outlet control system. This filter should also be isolated with suitable valves to enable scheduled filter element replacement without the need to drain the entire system. Ideally the buffer vessel outlet and nitrogen generator buffer return isolating valves, fulfil this purpose.

System integrity

It is essential to ensure that the complete system is gas tight, otherwise, especially with ppm units, it may not be possible to achieve purity. The connections, fittings and inspection hole seals on the buffer vessel are often a source of leaks and extra care must be taken to make sure everything is sealed using suitable leak detection methods. Not only will this maintain gas purity but also prevent the generator from starting up from economy stand-by, caused by a pressure drop from leaking pipe-work and vessels.
